## 1 Task 1 : Natural frequency

We make the following assumptions :

1. We will analyse the bridge under longitudinal flexion
2. We consider that the liaison between the HEM140 on the middle of the bridge is such that it can be considered as a full length HEM140 beam in the longitudinal axis.
3. Any other element than the HEM140 do not have any structural influence on the behaviour of the bridge (considering the connection consisting of 4 bolts is not sufficient to have them take any effort in their secondary axis), except for their weight. In particular, this means we can consider :

$$EI = \text{const} = 2 * EI_{HEM140}$$

4. We modelise the bridge as a beam on two supports, one of which is mobile
5. The weight of the cord is considered to be 0.4 kg/m

Properties of the different elements, as well as of the bridge, are taken from the C5 table.

In order to estimate the natural frequency, we will start with reducing the footbridge as a SDOF system, using the method provided [*Systems with distributed mass*, Aline Bönzli].

In order to do so, we will modelise the mass of the bridge and it's rigidity in python : (using a precision to the milimeter for the computation)

[2]: *# Properties of steel :*

*E = 210e3 #N/mm<sup>2</sup>*

*rho = 7850 #kg/m<sup>3</sup>*

*# Rigidity :*

*EI = 2 \* E \* (32.9e6) #N.mm<sup>2</sup>*

[3]: *# Define coordinates :*

*# - x : longitudinal axis (0 at first appui)*

*m\_IPE180 = 9.40 \* 0.155 - (0.050 \* 0.155 \* 0.0053)/2 \* rho #kg*

*# - 2\*ROR 51.5.0 L=1330 mm*

*m\_ROR = 5.67 \* 1.33 #kg*

*# - 2\*tubes dint=35mm, dext=38mm, L=50mm*

*m\_tubes = (np.pi \* ((19e-3)\*\*2 - (17.5e-3)\*\*2) \* 50e-3) \* rho #kg*

*# - 2\*rondelles*

*m\_rondelles = (np.pi \* (27e-3)\*\*2 \* 6e-3) \* rho #kg*

```

m_transversal = 1*m_HEA100 + 4*m_FLA + 2*m_IPE180 + 2*m_ROR + 2*m_tubes +
↳2*m_rondelles

out("m_{transversal}", m_transversal, ".3n", "kg")
out("m_{HEA100}", m_HEA100, ".3n", "kg")
out("m_{FLA}", m_FLA, ".3n", "kg")
out("m_{IPE180}", m_IPE180, ".3n", "kg")
out("m_{ROR}", m_ROR, ".3n", "kg")
out("m_{tubes}", m_tubes, ".3n", "kg")
out("m_{rondelles}", m_rondelles, ".3n", "kg")

# These transversal elements are present at 6 locations :
x_trans = np.array([0, 2000, 4000, 6000, 8000, 10000]) #mm

# Bolts are present 30 mm from those locations
x_bolts = np.concatenate((x_trans-30, x_trans+30))

# Add the mass from the transversal elements :
m[[i(x) for x in x_bolts]] += m_transversal / 2 / dx #dividing by dx ensures
↳the mass is fully considered, even for dx != 1

```

$m_{transversal} = 37.3 \text{ kg}$

$m_{HEA100} = 13.1 \text{ kg}$

$m_{FLA} = 1.55 \text{ kg}$

$m_{IPE180} = 1.3 \text{ kg}$

$m_{ROR} = 7.54 \text{ kg}$

$m_{tubes} = 0.0675 \text{ kg}$

$m_{rondelles} = 0.108 \text{ kg}$

```

[6]: # Add the cord's mass
rho_cord = 0.400 #kg/m

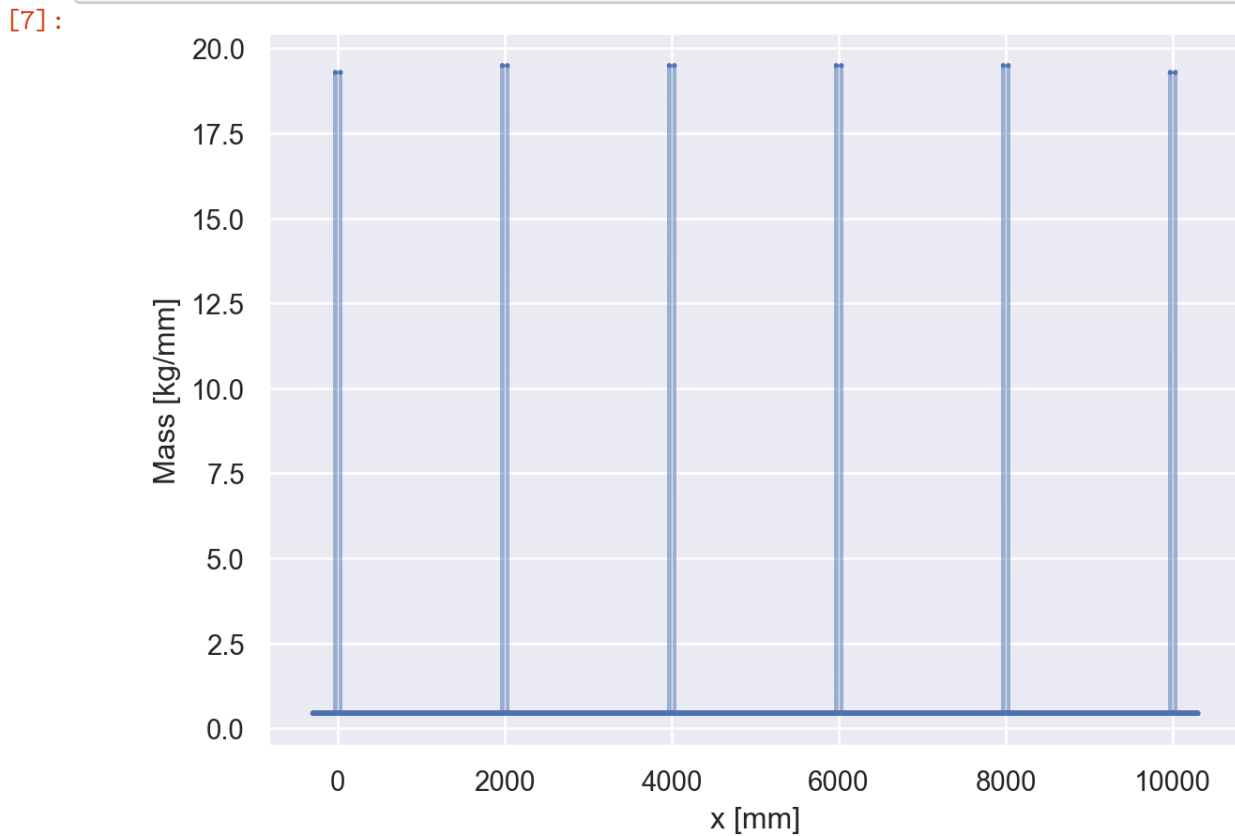

# We consider the poles have all to support 2m of cord, except the poles at
↳the end who supports only 1m
m_cord = 2* rho_cord #kg

x_bolts_2m = np.concatenate((x_trans[1:-1]-30, x_trans[1:-1]+30))
x_bolts_1m = np.concatenate((x_trans[[0,-1]]-30, x_trans[[0,-1]]+30))

m[[i(x) for x in x_bolts_2m]] += m_cord/2 /dx
m[[i(x) for x in x_bolts_1m]] += m_cord/4 /dx

```

```
[7]: (
    so.Plot(x=x, y=m)
    .add(so.Dot(pointsize=1.5))
    .add(so.Line(alpha=0.5))
    .label(x="x [mm]", y="Mass [kg/mm]")
    .plot()
)
```

Now that we have the mass, we need to define the bending shape. We will opt for a sine function, which will be equal to 0 at each support ( $x = 0$  and  $x = 10000$  [mm]). We consider that outside the supports, the beam will also deform in a sin shape.

$$\psi(x) = \sin\left(\frac{x * \pi}{10 \text{ m}}\right)$$

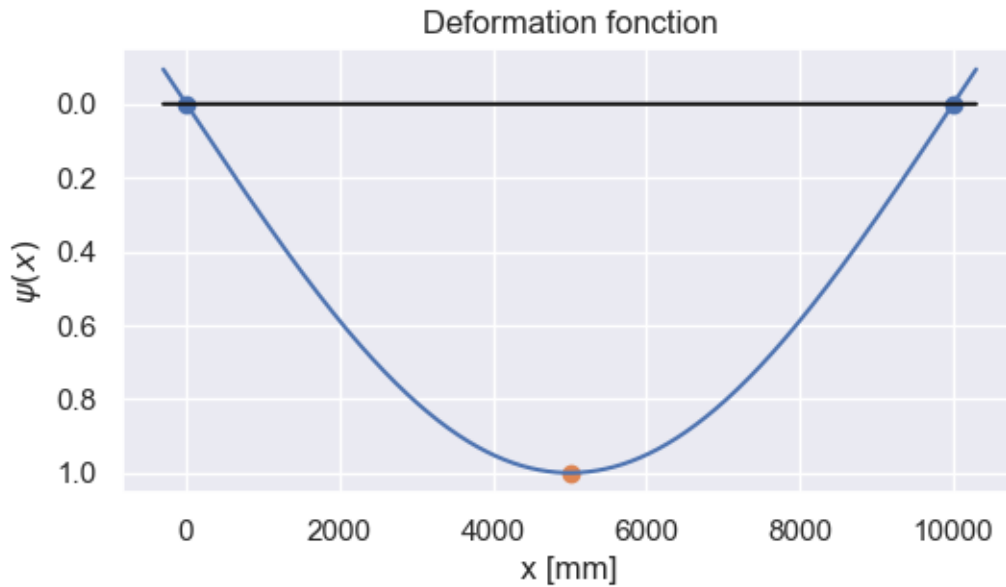

Which yields :

$$\psi''(x) = \psi(x) * \left(\frac{\pi}{10 \text{ m}}\right)^2$$

```
[8]: psi = np.sin(x*np.pi/10000)
psi_pp = psi * (np.pi/10000)**2 # -/mm2
```

```
[9]: plt.figure(figsize=(6, 3))
plt.plot(x, psi)
plt.plot(x, np.zeros_like(x), c="k")
plt.scatter([0, 10000], [0,0])
plt.scatter(x[i(5000)], psi[i(5000)])
plt.gca().invert_yaxis()
plt.title("Deformation fonction")
plt.xlabel("x [mm] ")
plt.ylabel("$\psi(x)$")

plt.show()
```

### Equivalent mass and stiffness

Now, we might compute the equivalent mass  $m^*$  and stiffness  $k^*$ :

$$m^* = \int_0^L m(x) * \psi^2(x) \, dx$$

$$k^* = EI * \int_0^L \psi''^2(x) \, dx$$

(considering that there are no normal force in the beam and EI is constant)

```
[10]: # Define integration algorithm

#integrate = np.trapz
```

```
integrate = lambda y, dx=1 : y.sum()*dx # Simpler and sure to include
↳ correctly the point masses # noqa: E731
```

```
[11]: m_star = integrate(m * psi**2, dx=dx) #kg
      k_star = EI * integrate(psi_pp**2, dx=dx) *1e3 #N/m

      out("m^*", m_star, ".0f", " kg")
      out("k^*", k_star/1000, ".0f", " kN/m")
```

$m^* = 2298 \text{ kg}$

$k^* = 673 \text{ kN/m}$

Now that we have reduced the system to a SDOF model, we can compute the natural period :

$$\omega_n = \sqrt{\frac{k^*}{m^*}}$$

```
[12]: omega_n = (k_star/m_star)**0.5
      T_n = 2*np.pi / omega_n
      f_n = omega_n /2 /np.pi

      out(r"\omega_n", omega_n, ".3", "[rad/s]")
      out(r"T_n", T_n, ".3", "s")
      out(r"f_n", f_n, ".3", "Hz")
```

$\omega_n = 17.1 \text{ [rad/s]}$

$T_n = 0.367 \text{ s}$

$f_n = 2.72 \text{ Hz}$

## 2 Task 2 : Response without tuned mass damper

We now compute the response of the bridge in two different load cases :

- Load case 1 : A person jumping at the natural frequency
- Load case 2 : A person walking across the bridge

### 2.1 Load case 1 : A person jumping at the natural frequency (2.72 Hz)

We make the following assumptions :

1. The person is jumping at the center of the bridge (the point of maximum amplitude of the mode)
2. The damping ratio of the bridge is 2%. This comes from a value cited multiple times in the lesson for steel structures (e.g. Week#10, “Modeling of damping”, slide 4 or Week#1, “Introduction”, slide 46)

Therefore, we use the following formula (Week#12 of the lesson) to compute the maximum acceleration under this load case :

$$a_{\max} = \omega_j^2 \cdot y \cdot \alpha \cdot \frac{1}{2\zeta}$$

With :

- $\omega_j$  the structural frequency that is in resonance with the forcing function (in this case,  $\omega_n$ )
- $y$  the static deflection of the bridge at mid-span for the weight  $G$  of the person standing at the point of maximum amplitude of the mode. We will take (typical assumption)  $G = 700N$
- $\alpha$  the fourier coefficient of the relevant harmonic. Here, we will take  $\alpha = 1.7$ , which corresponds to a person jumping at 3 Hz.
- $\zeta$  The damping ratio of the bridge :  $\zeta = 0.02$

To compute  $y$ , we will use the SDOF system we computed earlier. As such, we have :

$$y = \frac{G}{k^*}$$

```
[13]: # Data
G = 700 #N
L = 10e3 #mm
damp = 0.02
alpha = 1.7

# Previous results
print(f"EI : {EI:.2e} N.mm2 - omega_n : {omega_n:.1f} rad/s")
```

EI : 1.38e+13 N.mm<sup>2</sup> - omega\_n : 17.1 rad/s

```
[14]: # Computing y :
y = G / k_star * 1e3 #mm

out("y", y, ".3", "mm")
```

$y = 1.04 \text{ mm}$

```
[15]: # Computing a_max
a_max = omega_n**2 * y * alpha / 2 / damp * 1e-3 #m/s2

out("a_{max}", a_max, ".3", "m/s2")
```

$a_{\max} = 12.9 \text{ m/s}^2$

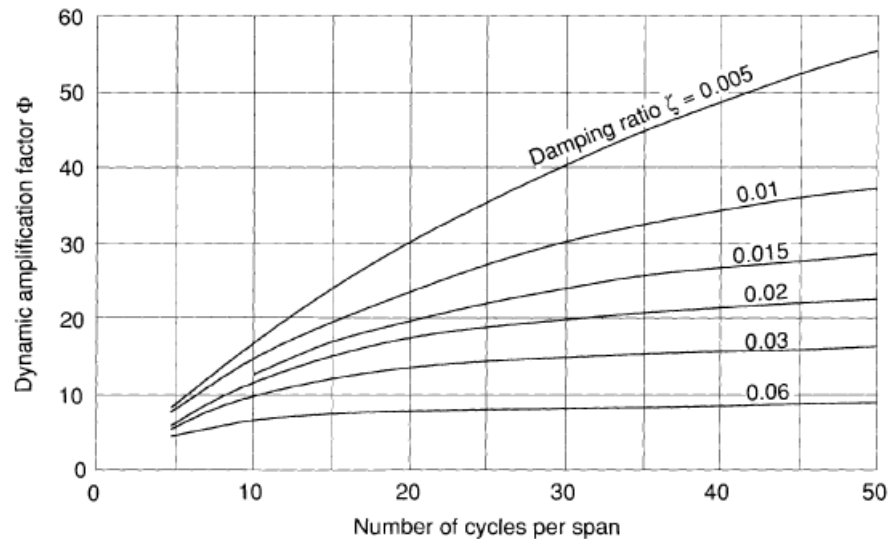

## 2.2 Load case 2 : A person walking accross the bridge

For a person walking accross the bridge, we will use a different formula :

$$a_{\max} = \omega_j^2 \cdot y \cdot \alpha \cdot \phi$$

Where  $\phi$  is a coefficient taking into account the damping, but also the fact that since the person is walking accross the bridge, the number of cycles is limited and the force is not always acting on

the most effective point. This coefficient can be determined from the following graph [Bachmann H et al. (1997). *Vibration problems in structures: practical guidelines*. Birkhäuser Verlag, 1995.] :

We will consider a footstep length of  $0.7m$  [Bachmann et al. (1997)], which means there will be, for a span of  $10\text{ m}$ ,  $n = \frac{10}{0.7} = 14.3$  cycles per span. For a damping ratio  $\zeta = 0.02$ , this represents a dynamic amplification factor of  $\psi = 14.5$ .

We also need to change the fourier coefficient  $\alpha$ , which for a person walking we will take  $\alpha = 0.4$

```
[16]: psi = 14.5
      alpha_2=0.4

      # Computing a_max
      a_max_2 = omega_n**2 * y*1e-3 * alpha_2 * psi #m/s^2
      out("a_{max, 2}", a_max_2, ".3", "m/s^2")
```

$$a_{max,2} = 1.77 \text{ m/s}^2$$

**Why is the response due to Load case 2 smaller than for Load case 1 ?**

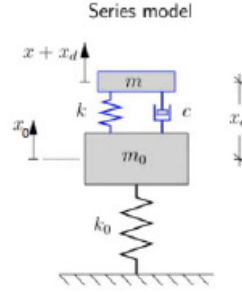

There are multiple reasons explaining why the response from load case 2 is smaller than the response from load case 1 :

- Firstly, a person walking generates less energy than a person jumping, which explains partly why the response is smaller.
- Secondly, in load case 2 the person is considered to be walking accross the bridge. As such, the person is not always at the most efficient point (the middle of the bridge) and the number of cycles is limited. As such, the steady-state will not be reached.

### 3 Task 3 : Response with Tuned Mass Damper (TMD)

The problem can be modelised as the following one (source: Week#12 of the lesson):

We are in the presence of a 2 degrees of freedom system, with the first degree of freedom corresponding to the SDOF calculated in Task 1 (on the schema, with mass  $m_0 = m^*$ , stiffness  $k_0 = k^*$  and displacement  $x_0(t)$ ) and the second degree of freedom being the TMD (with mass  $m$ , stiffness  $k$  and displacement  $x_d$ ).

We are going to estimate the steady-state response of the bridge with the TMD to an harmonic excitation with the natural frequency of the bridge. As such, the excitation on the first degree of freedom will be modelised as  $f(t) = f_0 \cdot e^{i\omega_n t}$ .

As we are analysing the steady-state response, the response will have the same frequency as the excitation, which yields :

$$x_0(t) = x_0 \cdot e^{i\omega_n t} \rightarrow \ddot{x}_0(t) = -\omega_n^2 \cdot x_0 \cdot e^{i\omega_n t}$$

As such, the maximum acceleration will be  $a_{max} = \omega_n^2 \cdot x_0$

In order to get  $x_0$ , we will compute the Dynamic Amplification Factor, using the following result of the lesson :

$$DAF = \frac{|x_0|}{f_0/k_0} = \frac{\sqrt{A^2 + (2\zeta_d)^2 B^2}}{\sqrt{C^2 + (2\zeta_d)^2 D^2}}$$

With :

- $A = \omega_0^2 [\omega_d^2 - \omega^2]$
- $B = \omega_d \cdot \omega \cdot \omega_0^2$
- $C = \omega^4 - [\omega_0^2 + (1 + \mu)\omega_d^2] \omega^2 + \omega_0^2 \omega_d^2$
- $D = \zeta_d \cdot \omega_d \omega [\omega_0^2 - (1 + \mu)\omega^2]$

And :

- $\mu$  : Mass ratio ( $\mu = m/m_0$ )
- $\zeta_d$  : Damping ratio of TMD
- $\omega_0$  : Frequency of structure ( $\omega_0 = \omega_n$ )
- $\omega_d$  : Frequency of TMD ( $\omega_d = 2.44 \cdot 2\pi$  rad/s)
- $\omega$  : Frequency of excitation ( $\omega = \omega_n$ )

Since  $\omega = \omega_0 = \omega_n$ , we can rewrite A, B, C, D :

- $A = \omega_n^2 \omega_d^2 - \omega_n^4$
- $B = \omega_d \omega_n^3$

- $C = \omega_n^4 - [\omega_n^2 + (1 + \mu)\omega_d^2] \omega_n^2 + \omega_n^2 \omega_d^2 = -\mu \omega_d^2 \omega_n^2$
- $D = \zeta_d \cdot \omega_d \omega_n [\omega_n^2 - (1 + \mu)\omega_n^2] = -\zeta_d \cdot \mu \cdot \omega_d \omega_n^3$

```
[17]: # Given
m_d = 140 #kg
omega_d = 2.44 * 2 * np.pi #rad/s
zeta_d = 0.12
```

```
[18]: # Compute A, B, C, D
mu = m_d / m_star
out(r"\mu", mu, ".3f", "")

A = omega_n**2 * omega_d**2 - omega_n**4
B = omega_d * omega_n**3
C = - mu * omega_d**2 * omega_n**2
D = - zeta_d * mu * omega_d * omega_n**3

print(f"A : {A:.3}, B : {B:.3}, C : {C:.3}, D : {D:.3}")

#compute the DAF :
DAF = (A**2 + (2*zeta_d*B)**2)**0.5 / (C**2 + (2*zeta_d*D)**2)**0.5

out(r"DAF = \frac{|x_0|}{f_0/k_0}", DAF, ".3f")
```

$$\mu = 0.061$$

$$A : -1.7\text{e}+04, B : 7.69\text{e}+04, C : -4.19\text{e}+03, D : -5.62\text{e}+02$$

$$DAF = \frac{|x_0|}{f_0/k_0} = 5.973$$

We will consider, in a similar fashion to what we did in Task 2, that the forcing function is the first harmonic of someone jumping, and therefore that  $f_0 = \alpha_{jumping} * G$ , with  $G = 700 \text{ N}$

With this result, we can compute  $|x_0|$  and therefore  $a_{max}$  :

```
[19]: f_0 = alpha * G #N
out("f_0", f_0, ".0f", "N")

x_0 = f_0 / k_star * DAF #m
out("|x_0|", x_0, unit="m")

a_max_3 = (omega_n)**2 * x_0 #m/s^2
out("a_{max}", a_max_3, unit="m/s^2")
```

$$f_0 = 1190 \text{ N}$$

$$|x_0| = 0.0106 \text{ m}$$

$$a_{max} = 3.09 \text{ m/s}^2$$
